ABSTRACT

A method of combined intercropping and mulching of commercial crops is described herein. A
10 suitable annual such as buckwheat is planted in soil in which legumes were originally planted. A
portion of the resulting wheat grass is mowed and blended with organic debris to provide
nutrients for intercropped commercial plants such as corn and soybeans. The remaining portion
is blended with organic debris and sprayed onto the top layer of seeded soil as combination
mulch. For larger commercial applications, conventional agricultural machines are described
15 herein, and are modified for the most efficient intercropping. For best results, at least one
intercropped commercial plant should be a legume.
